

## MATLAB Onramp

### Conclusion

### Summary

Summary of MATLAB Onramp

## Basic Syntax

| Example                  | Description                                                                                                                                  |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x = pi</code>      | Create variables and assign values with the equal sign (=).<br>The left side (x) is the variable name, and the right side (pi) is its value. |
| <code>y = sin(-5)</code> | Provide inputs to a function using parentheses.                                                                                              |

## Desktop Management

| Function            | Example                    | Description                                              |
|---------------------|----------------------------|----------------------------------------------------------|
| <code>save</code>   | save <code>data.mat</code> | Save your current workspace to a MAT-file.               |
| <code>load</code>   | load <code>data.mat</code> | Load the variables in a MAT-file to the workspace.       |
| <code>clear</code>  | clear                      | Clear all variables from the workspace.                  |
| <code>clc</code>    | clc                        | Clear all text from the Command Window.                  |
| <code>format</code> | format <code>long</code>   | Change how numeric output appears in the Command Window. |

## Array Types

| Example                     | Description   |
|-----------------------------|---------------|
| <code>4</code>              | scalar        |
| <code>[3 5]</code>          | row vector    |
| <code>[1;3]</code>          | column vector |
| <code>[3 4 5; 6 7 8]</code> | matrix        |

## Evenly Spaced Vectors

| Example                       | Description                                                                                |
|-------------------------------|--------------------------------------------------------------------------------------------|
| <code>1:4</code>              | Create a vector from 1 to 4, spaced by 1, using the <a href="#">colon operator ( : )</a> . |
| <code>1:0.5:4</code>          | Create a vector from 1 to 4, spaced by 0.5.                                                |
| <code>linspace(1,10,5)</code> | Create a vector with 5 elements. The values are evenly spaced from 1 to 10.                |

## Matrix Creation

| Example                 | Description                                                  |
|-------------------------|--------------------------------------------------------------|
| <code>rand(2)</code>    | Create a square matrix with 2 rows and 2 columns.            |
| <code>zeros(2,3)</code> | Create a rectangular matrix with 2 rows and 3 columns of 0s. |

|                        |                                                               |
|------------------------|---------------------------------------------------------------|
| <code>ones(2,3)</code> | Create a rectangular matrix with 2 rows and 3 columns of 1 s. |
|------------------------|---------------------------------------------------------------|

Array Indexing

| Example                | Description                                               |
|------------------------|-----------------------------------------------------------|
| <code>A(end,2)</code>  | Access the element in the second column of the last row.  |
| <code>A(2,:)</code>    | Access the entire second row.                             |
| <code>A(1:3,:)</code>  | Access all columns of the first three rows.               |
| <code>A(2) = 11</code> | Change the value of the second element of an array to 11. |

Array Operations

| Example                                                    | Description                                           |
|------------------------------------------------------------|-------------------------------------------------------|
| <code>[1 2; 3 4] + 1</code><br>ans =<br>2 3<br>4 5         | Perform <a href="#">array addition</a> .              |
| <code>[1 1; 1 1]*[2 2; 2 2]</code><br>ans =<br>4 4<br>4 4  | Perform <a href="#">matrix multiplication</a> .       |
| <code>[1 1; 1 1].*[2 2; 2 2]</code><br>ans =<br>2 2<br>2 2 | Perform <a href="#">element-wise multiplication</a> . |

Multiple Outputs

| Example                            | Description                                                          |
|------------------------------------|----------------------------------------------------------------------|
| <code>[xrow,xcol] = size(x)</code> | Save the number of rows and columns in x to two different variables. |
| <code>[xMax,idx] = max(x)</code>   | Calculate the maximum value of x and its corresponding index value.  |

Documentation

| Example                | Description                                         |
|------------------------|-----------------------------------------------------|
| <code>doc randi</code> | Open the documentation page for the randi function. |

Plots

| Example                                              | Description                                                                        |
|------------------------------------------------------|------------------------------------------------------------------------------------|
| <code>plot(x,y,"ro--",LineWidth=5)</code>            | Plot a red (r) dashed (--) line with a circle (o) marker, with a heavy line width. |
| <code>hold on</code>                                 | Add the next line to the existing plot.                                            |
| <code>hold off</code>                                | Create new axes for the next plotted line.                                         |
| <code>title("My Title")</code>                       | Add a title to a plot.                                                             |
| <code>xlabel("x")</code><br><code>ylabel("y")</code> | Add labels to axes.                                                                |
| <code>legend("a","b","c")</code>                     | Add a legend to a plot.                                                            |

## Tables

| Example                                                  | Description                                           |
|----------------------------------------------------------|-------------------------------------------------------|
| <code>data.HeightYards</code>                            | Extract the variable HeightYards from the table data. |
| <code>data.HeightMeters = data.HeightYards*0.9144</code> | Derive a table variable from existing data.           |

## Logical Indexing

| Example                        | Description                                                     |
|--------------------------------|-----------------------------------------------------------------|
| <code>[5 10 15] &gt; 12</code> | Compare the elements of a vector to the value 12.               |
| <code>v1(v1 &gt; 6)</code>     | Extract all elements of v1 that are greater than 6.             |
| <code>x(x==999) = 1</code>     | Replace all values in x that are equal to 999 with the value 1. |

## Programming

| Example                                                 | Description                                                                                                                 |
|---------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <pre> if x &gt; 0.5     y = 3 else     y = 4 end </pre> | <p>If x is greater than 0.5, set y to 3.</p> <p>Otherwise, set y to 4.</p>                                                  |
| <pre> for c = 1:3     disp(c) end </pre>                | <p>The loop counter (c) progresses through the values 1:3 (1, 2, and 3).</p> <p>The loop body displays each value of c.</p> |
